
Final Deliverables Guidelines

3-Month Teams

Two deliverables at the end of the cycle: **a report** and **a video**. The report carries the technical and strategic case; the video shows the system working.

2.1 Format

Length	10 pages maximum of body content
Font	11pt serif body (Times New Roman, Charter, or equivalent); 9pt minimum for figure captions and tables
Line spacing	Single
File format	PDF only <code>TeamName_FinalReport_v1.pdf</code>
Excluded from page count	Cover page (incl. abstract), references, appendices
Included in page count	All body sections, figures, and tables
Cover page	Project title, team members and affiliations, mentor/advisor, date, and the 250-word abstract – problem, approach, headline quantitative result, operational implication.
Appendices	5 pages max. Raw data, extended derivations, full test logs, supplementary photographs.
References	Unlimited, excluded from the page count. IEEE style recommended.

2.2 Recommended Sections and Page Budget

RESEARCH & TECHNICAL CORE ~7 PAGES

Introduction & Problem Statement

~0.5 pg

The operational gap: who the end user is, what they can't do today, what that costs. Your specific contribution. A short before-and-after – what existed on 21 June versus what exists now.

Prior Work & Competitive Landscape

~0.5 pg

Prior work: what's been published or demonstrated, including approaches tried and abandoned. Cite it.

Competitive landscape: what a system owner could buy today – primes, commercial dual-use products, allied or adversary fielded systems.

Technical Approach

~3.5 pg

Algorithm, hardware, or system – detailed enough for a competent engineer to follow and critique. Key design decisions: what you considered, what you ruled out, why. The assumptions the approach rests on. Derivations, schematics, pseudocode, or interface specs where they help.

Test Methodology

~1.5 pg

What you tested, under what conditions, against what baseline, and against success criteria set before you ran anything. Setup, instrumentation, trial count, controlled variables. TRL entry and exit, and the evidence behind the exit claim. Robustness: how the system holds up under the degraded conditions your mission involves – jamming and RF contest, GPS denial or spoofing, comms loss, sensor dropout or occlusion, night and low light, weather, clutter and multipath, vibration and thermal stress, adversarial or out-of-distribution inputs. Name what you didn't test rather than omitting it.

Results & Discussion

~1 pg

Numbers with uncertainty, against the baseline. Limitations, failure modes, anything that surprised you. Cost alongside performance – hardware: expected unit cost of the working prototype, projected cost at volume. Software: cost to serve, compute footprint, what breaks at scale. Effectors: cost-exchange, price per shot against the price of the threat you defeat. If the exchange runs the wrong way, say so and say what closes it.

STRATEGY & TRANSITION ~3 PAGES

Possible Defense Applications (CONOPS)

~1.0 pg

Primary application in operational detail: end user, the mission thread just before and after your system is used, deployment constraints (platform, power, SWaP, connectivity, environment), failure behaviour – safe, loud, or silent – operator training burden. Then the secondary mission sets the same core technology could serve, and what would have to change for each. Label assumptions as assumptions. Show-stopper risks: named early – the technical and operational risks that could kill this as a programme, not the ones you've retired. Integration and no lock-in (MOSA): interfaces and data contracts, concrete enough that a MINDEF or SAF system owner can tell whether this drops in as a swappable node and comes back out later without stranding the investment. Cover sovereign control of the system and its data, and any dependency – foreign-controlled black box, licence, cloud service – that could be withdrawn.

Defensibility

~0.5 pg

Why can't someone else build this, and why will yours be the best? Whichever apply: a data advantage that can't be bought or recreated, an integration or accreditation moat, cost or manufacturing structure with real numbers, switching costs once installed, tacit knowledge tied to something concrete. Quantify what a well-funded competitor would spend, in time and money, to reach parity. Say where you win head-to-head against the closest alternative in your landscape table, and where you don't.

Incubation Plan

~1.5 pg

Route to a buyer: who inside MINDEF/SAF would sponsor this, what a first realistic contract or trial looks like, what has to be true for it to happen. Next six months: milestones and TRL you'd target, the biggest remaining unknown and the specific experiment or build that retires it, capability gaps and partnerships you'd go after first. Be specific; don't oversell. How you'd deploy funding: hires, hardware, test time, tooling, certification. Optional asks: what you need that you can't get yourselves – an operator conversation, a test site, a component, a partner team. Unsourced.

03

Video

Footage of the system, watched alongside the report

3.1 Format

Length	2 minutes maximum
File format	MP4 <code>TeamName_Demo.mp4</code> , plus an unlisted streaming link as backup
Opening card	Project title, team members, mentor/advisor, date
Scope	The video is watched alongside the report, not instead of it. No problem framing, no pitch, no architecture walkthrough – the report carries all of that. Footage of the system only.
Labelling	Identify each clip on screen or in narration: what we're looking at, and under what conditions.

3.2 What to Cover

We suggest covering the system in **nominal operation**, the **test environment** behind your results, **robustness testing** under the degraded conditions from your test methodology, and **failure modes** – where it breaks and what happens when it does. Weight them however your project warrants.

3.3 Further Notes

Label anything that isn't real footage of your system – simulated, rendered, animated, staged, re-enacted, or sped up. On screen, at the moment it appears.

Production quality isn't scored. Phone footage of a working prototype beats a polished render of a concept.

Questions?

Ask your mentor, or DVL programme staff.
